Exercise: Encapsulation

Problems for exercise and homework for the "C# OOP" course @ SoftUni".

You can check your solutions here: https://judge.softuni.org/Contests/1498/Encapsulation-Exercise

1. Class Box Data

Create a class **Box**, which has the following properties:

- Length double, should not be zero or negative number
- Width double, should not be zero or negative number
- **Height** double, should not be zero or negative number

If one of the properties is a zero or negative number throw ArgumentException with the message: "{propertyName} cannot be zero or negative." Use try-catch block to process the error. All properties are set by the constructor and when set, they cannot be modified.

Behavior

double SurfaceArea()

Calculate and return the surface area of the Box.

double LateralSurfaceArea()

Calculate and return the lateral surface area of the Box.

double Volume()

Calculate and return the volume of the Box.

NOTE: You can find all formulas here.

Input

On the first three lines, you will get the length, width, and height.

Output

On the next three lines print the surface area, lateral surface area, and the volume of the box.

Examples

Input	Output
2	Surface Area - 52.00
3	Lateral Surface Area - 40.00
4	Volume - 24.00
1.3	Surface Area - 30.20
1	Lateral Surface Area - 27.60
6	Volume - 7.80
2	Width cannot be zero or negative.
-3	
4	

2. Animal Farm

For this problem, you have to download the provided skeleton.

You should be familiar with encapsulation already. For this problem, you'll be working with the AnimalFarm project. It contains a class Chicken. Chicken contains several fields, a constructor, several properties, and methods. Your task is to encapsulate or hide anything unintended for viewing or modification from outside the class.

Step 1. Encapsulate Fields

Fields should be private. Leaving fields open for modification from outside the class is potentially dangerous. Make all fields in the Chicken class private. In case the value inside the field is needed elsewhere, use getters to reveal it.

Step 2. Ensure Classes Have a Correct State

Having getters and setters is useless if you don't use them. The Chicken constructor modifies the fields directly, which is wrong when there are suitable setters available. Modify the constructor to fix this issue.

Step 3. Validate Data Properly

Validate the chicken's name (it cannot be null, empty, or whitespace). In case of an invalid name, print the Exception message: "Name cannot be empty.".

Validate the age properly, minimum and maximum age are provided, make use of them. In case of an invalid age, print Exception message: "Age should be between 0 and 15.". Don't forget to handle properly the possibly thrown **Exceptions**.

Step 4. Hide Internal Logic

If a method is intended to be used only by descendant classes or internally to perform some action, there is no point in keeping them public. The CalculateProductPerDay() method is used by the ProductPerDay public getter. This means the method can safely be hidden inside the Chicken class by declaring it private.

Step 5. Submit Code to Judge

Submit your code as a zip file in Judge. Zip everything except the bin and obj folders within the project and submit the single zip file in judge.

Examples

Input	Output
Molly 10	Chicken Molly (age 10) can produce 1 eggs per day.
Molly 17	Age should be between 0 and 15.

3. Shopping Spree

Create two classes:

- Person
- Product

Each **person** should have a **name**, **money**, and a **bag of products**. Each **product** should have a **name** and a **cost**. The name cannot be an **empty string**. Money cannot be a **negative number**.

Create a program where each command corresponds to a person buying a product. If the person can afford a product, add it to his bag. If a person doesn't have enough money, print an appropriate message ("{personName} can't afford {productName}").

On the first two lines, you are given all people and all products. After all, purchases print every person in the order of appearance and all products that he has bought also in order of appearance. If nothing was bought, print the name of the person followed by "Nothing bought".

In case of invalid input (negative money Exception message: "Money cannot be negative") or an empty name (empty name Exception message: "Name cannot be empty") break the program with an appropriate message. See the examples below:

Examples

Input	Output
Peter=11;George=4	Peter bought Bread
Bread=10;Milk=2;	George bought Milk
Peter Bread	George bought Milk
George Milk	Peter can't afford Milk
George Milk	Peter - Bread
Peter Milk	George - Milk, Milk
END	
Maria=0	Maria can't afford Coffee
Coffee=2	Maria - Nothing bought
Maria Coffee	
END	
John=-3	Money cannot be negative
Peppers=1;Tomatoes=2;Cheese=3	
John Peppers	
John Tomatoes	
John Cheese	
END	

4. Pizza Calories

A pizza is made of dough and different toppings. You should model a class Pizza, which should have a name, dough, and toppings as fields. Every type of ingredient should have its class. Every ingredient has different properties: the dough can be white or wholegrain and in addition, it can be crispy, chewy, or homemade. The topping can be of type meat, veggies, cheese, or sauce. Every ingredient should weigh grams and a method for calculating its calories according to its type. Calories per gram are calculated through modifiers. Every ingredient has 2 calories per gram as a base and a modifier that gives the exact calories. For example, a white dough has a modifier of 1.5, a chewy dough has a modifier of 1.1, which means that a white chewy dough, weighing 100 grams will have 2 * 100 * 1.5 * 1.1 = 330.00 total calories.

Your job is to model the classes in such a way that they are properly encapsulated and to provide a public method for every pizza that calculates its calories according to the ingredients it has.

Step 1. Create a Dough Class

The base ingredient of a Pizza is the dough. First, you need to create a class for it. It has a flour type, which can be white or wholegrain. In addition, it has a baking technique, which can be crispy, chewy, or homemade. The dough should weigh grams. The calories per gram of dough are calculated depending on the flour type and the baking technique. Every dough has 2 calories per gram as a base and a modifier that gives the exact calories. For example, a white dough has a modifier of 1.5, a chewy dough has a modifier of 1.1, which means that a white chewy dough, weighing **100** grams will have (2 * 100) * 1.5 * 1.1 = 330.00 total calories. You are given the modifiers below:

Modifiers:

- White 1.5
- Wholegrain 1.0
- Crispy 0.9
- Chewy 1.1
- Homemade 1.0

Everything that the class should expose is a getter for the calories per gram. Your task is to create the class with a proper constructor, fields, getters, and setters. Make sure you use the proper access modifiers.

Step 2. Validate Data for the Dough Class

Change the internal logic of the **Dough** class by adding a **data validation** in the **setters**.

Make sure that if an invalid flour type or an invalid baking technique is given a proper Exception is thrown with the message "Invalid type of dough.".

The allowed weight of dough is in the range [1..200] grams. If it is outside of this range throw an Exception with the message "Dough weight should be in the range [1..200].".

Exception Messages

- "Invalid type of dough."
- "Dough weight should be in the range [1..200]."

Make a test in your main method that reads Doughs and prints their calories until an "END" command is given.

Examples

Input	Output
Dough White Chewy 100 END	330.00
Dough Tip500 Chewy 100 END	Invalid type of dough.
Dough White Chewy 240 END	Dough weight should be in the range [1200].

Step 3. Create a Topping Class

Next, you need to create a **Topping class**. It can be of four different types - **meat**, **veggies**, **cheese**, or a **sauce**. A Topping weights grams. The calories per gram of topping are calculated depending on its type. The base calories per gram are 2. Every different type of topping has a modifier. For example, meat has a modifier of 1.2, so a meat topping will have 1.2 calories per gram (1 * 1.2). Everything that the class should expose is a getter for calories per gram. You are given the modifiers below:

Modifiers:

- Meat 1.2;
- Veggies 0.8;
- Cheese 1.1;
- Sauce 0.9;

Your task is to create the class with a proper constructor, fields, getters, and setters. Make sure you use the proper access modifiers.

Step 4. Validate Data for the Topping Class

Change the internal logic of the **Topping** class by adding **data validation** in the **setter**.

Make sure the **Topping** is one of the provided types, otherwise throw a proper **Exception** with the message "Cannot place [name of invalid argument] on top of your pizza.".

The allowed weight of a **Topping** is in the range [1..50] grams. If it is **outside of this range** throw an **Exception** with the message "[Topping type name] weight should be in the range [1..50].".

Exception Messages

- "Cannot place [name of invalid argument] on top of your pizza."
- "[Topping type name] weight should be in the range [1..50]."

Make a test in your main method that reads a single dough and a topping after that and prints their calories.

Examples

Input	Output
Dough White Chewy 100	330.00
Topping meat 30	72.00
END	
Dough White chewy 100	330.00
Topping Krenvirshi 500	Cannot place Krenvirshi on top of your pizza.
END	
Dough White Chewy 100	330.00
Topping Meat 500	Meat weight should be in the range [150].
END	

Step 5. Create a Pizza Class!

A Pizza should have a name, some toppings, and dough. Make use of the two classes you made earlier. In addition, a Pizza should have public getters for its name, the number of toppings, and the total calories. The total calories are calculated by summing the calories of all the ingredients a Pizza has. Create the class using a proper constructor, expose a method for adding a topping, a public setter for the dough, and a getter for the total calories.

The input for a Pizza consists of several lines. On the first line is the Pizza name and on the second line, you will get input for the dough. On the next lines, you will receive every topping the Pizza has.

If the creation of the Pizza was successful, print on a single line the name of the Pizza and the total calories it has.

Step 6. Validate Data for the Pizza Class

The name of the Pizza should not be an empty string. In addition, it should not be longer than 15 symbols. If it does not fit, throw an Exception with the message "Pizza name should be between 1 and 15 symbols.".

The number of toppings should be in the range [0..10]. If not, throw an Exception with the message "Number of toppings should be in range [0..10].".

Your task is to print the name of the Pizza and the total calories it has according to the examples below.

Examples

Input	Output
Pizza Meatless Dough Wholegrain Crispy 100 Topping Veggies 50 Topping Cheese 50 END	Meatless - 370.00 Calories.
Pizza Burgas Dough White Homemade 200 Topping Meat 123 END	Meat weight should be in the range [150].
Pizza Bulgarian Dough White Chewy 100 Topping Sauce 20 Topping Cheese 50 Topping Cheese 40 Topping Meat 10 Topping Sauce 10 Topping Cheese 30 Topping Cheese 40 Topping Meat 20 Topping Sauce 30 Topping Sauce 30 Topping Cheese 25 Topping Cheese 40 Topping Meat 40 END	Number of toppings should be in range [010].
Pizza Bulgarian Dough White Chewy 100 Topping Sirene 50 Topping Cheese 50 Topping Krenvirsh 20 Topping Meat 10 END	Cannot place Sirene on top of your pizza.

5. **Football Team Generator

A football Team has a variable number of players, a name, and a rating. A Player has a name and stats, which are the basis for his skill level. The stats a player has are endurance, sprint, dribble, passing, and shooting. Each stat can be an integer in the range [0..100]. The overall skill level of a player is calculated as the average of his stats. Only the name of a player and his stats should be visible to the entire outside world. Everything else should be hidden.

A Team should expose a name, a rating (calculated by the average skill level of all players in the team and rounded to the integer part only), and methods for adding and removing players.

Your task is to model the Team and the Player classes following the proper principles of Encapsulation. Expose only the properties that need to be visible and validate data appropriately.

Input

Your application will receive commands until the "END" command is given. The command can be one of the following:

- "Team;{TeamName}" add a new Team;
- "Add;{TeamName};{PlayerName};{Endurance};{Sprint};{Dribble};{Passing};{Shooting}" add a new Player to the Team;
- "Remove;{TeamName};{PlayerName}" remove the Player from the Team;
- "Rating;{TeamName}" print the Team rating, rounded to an integer.

Data Validation

- A name cannot be null, empty, or white space. If not, print "A name should not be empty."
- Stats should be in the range 0..100. If not, print "[Stat name] should be between 0 and 100."
- If you receive a command to remove a missing Player, print "Player [Player name] is not in [Team name] team."
- If you receive a command to add a Player to a missing Team, print "Team [team name] does not
- If you receive a command to show stats for a missing **Team**, print **"Team [team name] does not** exist."

Examples

Input	Output
Team;Arsenal Add;Arsenal;Kieran_Gibbs;75;85;84;92;67 Add;Arsenal;Aaron_Ramsey;95;82;82;89;68 Remove;Arsenal;Aaron_Ramsey Rating;Arsenal END	Arsenal - 81
Team;Arsenal Add;Arsenal;Kieran_Gibbs;75;85;84;92;67 Add;Arsenal;Aaron_Ramsey;195;82;82;89;68 Remove;Arsenal;Aaron_Ramsey Rating;Arsenal END	Endurance should be between 0 and 100. Player Aaron_Ramsey is not in Arsenal team. Arsenal - 81
Team;Arsenal Rating;Arsenal END	Arsenal - 0
